Model, Lattice, and Identity System

One-pager · The identity layer for multi-intelligence trust coordination

---

Identity in this system is not a root key. It is a path on a 6-dimensional sovereignty lattice — an accumulation of bilateral commitments, content-addressed and anchored across one or more chains.

Lattice. Configuration space is $\{0,1\}^6$ = 64 vertices. Each vertex address is a 6-bit string indicating which of six qualities are active in a single commitment:

Bit	Quality	Active when
d_1	Protection	Privacy boundary asserted
d_2	Delegation	Capability transferred
d_3	Memory	Prior history referenced
d_4	Connection	Multi-party coordination
d_5	Computation	ZK verification active
d_6	Value	Economic flow committed

Vertex distribution by stratum (Pascal's row, k = 0…6): **1, 6, 15, 20, 15, 6, 1 = 64.**

Identity. $\mathscr{I}$ = (DID, Π, $\mathscr{V}$, $\mathscr{A}$):

- **DID** is `did:cid:…` — a content-addressed principal.
- **Π** is the multiset of bilateral commitments held.
- $\mathscr{V}$ maps each commitment to its visibility ratio $\sigma \in [0,1]$.
- $\mathscr{A}$ maps each commitment to one or more chain anchors (Zcash, Bitcoin, Ethereum, IPFS, private mesh).

Identity value is computed against a path integral **T∫(π)** over the trajectory through Π — order-sensitive, not over the set alone.

Properties. No root key. No central holder. Multi-chain anchoring survives single-chain failure. Post-quantum by construction: no stored secret to invert. Substrate-neutral admissibility for counterparties of any intelligence class.
